## MAST90104: Introduction to Statistical Learning

## Week 3 Workshop and Lab

1. Suppose that X is a random variable with density function, f, given by

$$f(x) = \sum_{i=0}^{\infty} p(i)g(x;i)$$

where  $p(0), p(1), \cdots$  is a discrete probability mass function on  $\{0, 1, \cdots\}$  and each g(x; i) is a probability density function. Suppose that  $\mu(i), \sigma^2(i), M(t; i)$  are the mean, variance and moment generating function for the density g(x; i). Let M(t) be the moment generating function of X. Suppose also that N is a random variable with probability mass function  $p(i), i = 0, 1, \cdots$ . Show that

- (a)  $E(X) = E(\mu(N))$
- (b) var  $(X) = E(\sigma^2(N)) + \text{var } (\mu(N))$
- (c) M(t) = E(M(t; N)).

(Hint: You may assume that interchange of infinite sums and integrals is justified.)

2. Section 2.3 states that the density function, f, of a non-central chi-square random variable, X, with degrees of freedom k and non-centrality parameter  $\lambda$  has the form of f(x) in question 1. Further g(x;i) is the central chi-square density with k+2i degrees of freedom and  $p(0), p(1), \cdots$  is the pmf of the Poisson distribution with parameter  $\lambda$ . Use the results in question 1 to show that:

- (a) var  $(X) = 2k + 8\lambda$
- (b)  $M(t) = (1 2t)^{-k/2} e^{2\lambda t/(1-2t)}$ .
- 3. Use question 2 to prove Theorem 3.4.

4. Let  $\mathbf{y} = \begin{bmatrix} y_1 & y_2 \end{bmatrix}^T$  be a normal random vector with mean and variance

$$\mu = \begin{bmatrix} 2 \\ 4 \end{bmatrix}, \quad V = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}.$$

Let

$$A = \frac{1}{2} \left[ \begin{array}{cc} 1 & 1 \\ 1 & 1 \end{array} \right], \quad B = \frac{1}{2} \left[ \begin{array}{cc} 1 & -1 \\ -1 & 1 \end{array} \right].$$

- (a) Find the distributions of  $\mathbf{y}^T A \mathbf{y}$  and  $\mathbf{y}^T B \mathbf{y}$ .
- (b) Are  $\mathbf{y}^T A \mathbf{y}$  and  $\mathbf{y}^T B \mathbf{y}$  independent?
- (c) What is the distribution of  $\mathbf{y}^T A \mathbf{y} + \mathbf{y}^T B \mathbf{y}$ ?
- 5. Let  $y_1, \ldots, y_n$  be an i.i.d. normal sample. Show that

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i$$
 and  $s^2 = \frac{1}{n-1} \sum_{i=1}^{n} (y_i - \bar{y})^2$ 

are independent. (Hint: Express them as a random "vector" and quadratic form respectively.)

6. We model an individual's income at age 30 against the number of years of formal education with a linear model. The following data is collected:

1

Years of formal education $(x)$	Income ( $\$$ k) ( $y$ )
8	8
12	15
14	16
16	20
16	25
20	40

Where possible, solve the following questions in two ways: using matrix calculations as detailed in the lectures, and using the lm command in R.

- (a) Plot the data; is a linear model appropriate?
- (b) Write down the linear model in matrix form.
- (c) Find the normal equations for this model.
- (d) Solve the normal equations to obtain the least squares estimates of the parameters. Add the fitted regression line to your plot (using curve for example).
- (e) This model is a simple linear regression model. Use the standard linear regression formulae,

$$b_1 = \frac{\overline{xy} - \bar{x}\bar{y}}{\overline{x^2} - \bar{x}^2}, \quad b_0 = \bar{y} - b_1\bar{x},$$

to estimate the parameters again (where the bar indicates the mean). Check that you have the same answers as above.

- (f) Calculate the sample variance  $s^2$ .
- (g) Estimate the average income of a person who has had 18 years of formal education.
- (h) Calculate the standardised residuals, leverage, and Cook's distance for the first observation. You may need the R functions rstandard, influence, and cooks.distance. Check your numbers against the diagnostic plots produced by R.
- (i) We know that the least squares estimator **b** is an unbiased estimator for  $\beta$ . Show that  $\mathbf{t}^T \mathbf{b}$  is an unbiased estimator for  $\mathbf{t}^T \beta$ , where **t** is a vector of constants.

## R exercises

Read Sections 5.1–5.3 of spuRs (which is available electronically in the library), then attempt the exercises below.

- 7. The (Euclidean) length of a vector  $v = (a_0, \ldots, a_k)$  is the square root of the sum of squares of its coordinates, that is  $\sqrt{a_0^2 + \cdots + a_k^2}$ . Write a function that returns the length of a vector.
- 8. Last week you wrote a program to calculate h(x, n), the sum of a finite geometric series. Turn this program into a function that takes two arguments, x and n, and returns h(x, n).
  - Make sure you deal with the case x = 1.
- 9. In this question we simulate the rolling of a die. To do this we use the function runif(1), which returns a 'random' number in the range (0,1). To get a random integer in the range {1,2,3,4,5,6}, we use ceiling(6\*runif(1)), or if you prefer, sample(1:6,size=1) will do the same job.
  - (a) Suppose that you are playing the gambling game of the Chevalier de Méré. That is, you are betting that you get at least one six in four throws of a die. Write a program that simulates one round of this game and prints out whether you win or lose.
    - Check that your program can produce a different result each time you run it.
  - (b) Turn the program that you wrote in part (a) into a function sixes, which returns TRUE if you obtain at least one six in n rolls of a fair die, and returns FALSE otherwise. That is, the argument is the number of rolls n, and the value returned is TRUE if you get at least one six and FALSE otherwise.

How would you give n the default value of 4?

- (c) Now write a program that uses your function sixes from part (b), to simulate N plays of the game (each time you bet that you get at least one six in n rolls of a fair die). Your program should then determine the proportion of times you win the bet. This proportion is an estimate of the *probability* of getting at least one six in n rolls of a fair die.
  - Run the program for n = 4 and N = 100, 1000, and 10000, conducting several runs for each N value. How does the *variability* of your results depend on N?
  - The probability of getting no 6's in n rolls of a fair die is  $(5/6)^n$ , so the probability of getting at least one is  $1 (5/6)^n$ . Modify your program so that it calculates the theoretical probability as well as the simulation estimate and prints the difference between them. How does the accuracy of your results depend on N?
- (d) In part (c), instead of processing the simulated runs as we go, suppose we first store the results of every game in a file, then later postprocess the results. You should read spuRs Chapter 4 to see how to read and write text files.
  - Write a program to write the result of all N runs to a textfile  $sixes\_sim.txt$ , with the result of each run on a separate line. For example, the first few lines of the textfile could look like

TRUE FALSE FALSE TRUE FALSE

Now write another program to read the textfile sixes\_sim.txt and again determine the proportion of bets won.

This method of saving simulation results to a file is particularly important when each simulation takes a very long time (hours or days), in which case it is good to have a record of your results in case of a system crash.
